

Markov Chain Monte Carlo

Richard Xu

November 25, 2022

1 Topic Summary

In many data science scenarios, we need to model a latent variable of interest \mathbf{z} given data \mathbf{x} , for example, we may need to compute the following quantities:

$$\mathbb{E}_{p(\mathbf{z}|\mathbf{x})}[\mathbf{z}] \quad (1)$$

this can be approximated by:

$$\frac{1}{N} \sum_{i=1}^N \mathbf{z}^{(i)} \quad \mathbf{z}^{(i)} \sim p(\mathbf{z}|\mathbf{x}) \quad (2)$$

For example, in the LDA example:

$$\begin{aligned} \mathbf{x} &\equiv \{w_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\} \\ \mathbf{z} &\equiv \{\{\beta_j\}_{j=1}^K, \{\theta_d\}_{d=1}^D, \{z_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\}\} \end{aligned} \quad (3)$$

Therefore, in LDA, by obtaining samples from:

$$p\left(\underbrace{\{\beta_j\}_{j=1}^K, \{\theta_d\}_{d=1}^D, \{z_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\}}_{\mathbf{z}} \mid \underbrace{\{w_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\}}_{\mathbf{x}}\right) \quad (4)$$

it allows us to approximate:

$$\mathbb{E}\left[\left\{\{\beta_j\}_{j=1}^K, \{\theta_d\}_{d=1}^D, \{z_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\}\right\}\right] \quad (5)$$

Alternatively, you might be interested in computing $\arg \max_{\mathbf{z}} \{p(\mathbf{z}|\mathbf{x})\}$. This can be approximated as:

$$\arg \max \{p(\mathbf{z}^{(i)})\} \quad \mathbf{z}^{(i)} \sim p(\mathbf{z}|\mathbf{x}) \quad (6)$$

So you can see that both approximations require sampling $\mathbf{z} \sim p(\mathbf{z}|\mathbf{x})$. However, sampling may not always be straightforward to implement. Therefore, in this topic, we will discuss a sampling method called, Markov Chain Monte Carlo (MCMC).

2 Explain using finite dimensionality

2.1 Stochastic matrices

Right stochastic matrix (or row stochastic matrix) is a real square matrix, with **each row** summing to 1.

$$\begin{bmatrix} K_{1 \rightarrow 1} & \dots & K_{1 \rightarrow n} \\ \dots & \dots & \dots \\ K_{d \rightarrow 1} & \dots & K_{d \rightarrow n} \\ \dots & \dots & \dots \\ K_{n \rightarrow 1} & \dots & K_{n \rightarrow n} \end{bmatrix} \quad (7)$$

for example:

$$\begin{bmatrix} 0.3 & 0.2 & 0.5 \\ 0.05 & 0.9 & 0.05 \\ 0.7 & 0.2 & 0.1 \end{bmatrix} \quad (8)$$

Left stochastic matrix (or column stochastic matrix) is a real square matrix, with **each column** summing to 1

$$\begin{bmatrix} K_{1 \rightarrow 1} & \dots & K_{n \rightarrow 1} \\ \dots & \dots & \dots \\ K_{1 \rightarrow d} & \dots & K_{n \rightarrow d} \\ \dots & \dots & \dots \\ K_{1 \rightarrow n} & \dots & K_{n \rightarrow n} \end{bmatrix} \quad (9)$$

for example:

$$\begin{bmatrix} 0.3 & 0.05 & 0.7 \\ 0.2 & 0.9 & 0.2 \\ 0.5 & 0.05 & 0.1 \end{bmatrix} \quad (10)$$

doubly stochastic matrices: is a real square matrix, where both **each column** and **each row** summing to 1.

2.2 Product of two stochastic matrix is still stochastic

We choose both A and B to be **right stochastic matrix**, where each entry in the product $C = AB$ is a dot product of a row from A and a column from B :

$$C_{ij} = \sum_{k=1}^n A_{ik} B_{kj} \quad (11)$$

let's look at what if we sum over a row of AB , i.e., $C_{i,:}$:

$$\begin{aligned}\sum_{j=1}^n C_{ij} &= \sum_{j=1}^n \sum_{k=1}^n A_{ik} B_{kj} \\ &= \sum_{k=1}^n (A_{ik} \sum_{j=1}^n B_{kj})\end{aligned}\tag{12}$$

1. Because B is right stochastic, $\sum_{j=1}^n B_{kj} = 1$
2. Because A is right stochastic, $\sum_{k=1}^n A_{ik} = 1$

therefore, once again, the new product matrix $C = AB$ is a **right stochastic matrix**.

2.2.1 left stochastic matrix

We can show the similar result when A and B are **left stochastic matrix**:

$$\begin{aligned}\sum_{i=1}^n C_{ij} &= \sum_{i=1}^n \sum_{k=1}^n A_{ik} B_{kj} \\ &= \sum_{k=1}^n (B_{kj} \sum_{i=1}^n A_{ik}) \\ &= \sum_{k=1}^n B_{kj} \quad \because \sum_{i=1}^n A_{ik} = 1 \\ &= 1\end{aligned}\tag{13}$$

2.3 Perron-Frobenius Theorem:

Theorem 1 *If K is a left stochastic matrix, then, 1 is an eigenvalue of multiplicity one. (meaning 1 is the largest eigenvalue: all the other eigenvalues have absolute value smaller than 1), and the eigenvectors corresponding to the eigenvalue 1 have either only positive entries or only negative entries.*

3 Power Method Convergence Theorem

Let K be a positive, **left** (i.e., each column add to one) stochastic $n \times n$ matrix, and π^* be its **target** probabilistic eigenvector corresponding to the eigenvalue 1. then:

$$\begin{aligned}
\begin{bmatrix} K_{1 \rightarrow 1} & \dots & K_{n \rightarrow 1} \\ \dots & \dots & \dots \\ K_{1 \rightarrow n} & \dots & K_{n \rightarrow n} \end{bmatrix} \begin{bmatrix} \pi_1^* \\ \dots \\ \pi_n^* \end{bmatrix} &= \begin{bmatrix} \pi_1^* \\ \dots \\ \pi_n^* \end{bmatrix} \\
\implies \pi_d^* &= \sum_{i=1}^n \pi_i^* K_{i \rightarrow d}
\end{aligned} \tag{14}$$

we can verify $\sum_{d=1}^n \pi_d^* = 1$:

$$\begin{aligned}
\sum_{d=1}^n \pi_d^* &= \sum_{d=1}^n \sum_{i=1}^n \pi_i^* K_{i \rightarrow d} \\
&= \sum_{i=1}^n \pi_i^* \sum_{d=1}^n K_{i \rightarrow d} \\
&= 1
\end{aligned} \tag{15}$$

therefore, only when **left** stochastic matrix multiplies a **column** stochastic vector, results to another stochastic vector.

Let $\pi^{(1)}$ be the column vector with all entries equal to some arbitrary stochastic vector. Then sequence:

$$\{\pi^{(1)}, K\pi^{(1)}, K^2\pi^{(1)}, \dots, K^t\pi^{(1)}, \dots, K^\infty\pi^{(1)}\} \tag{16}$$

converges to the vector π^*

$$\lim_{t \rightarrow \infty} K^t = K^\infty \implies \lim_{t \rightarrow \infty} K^t \pi^{(1)} = \pi^* \tag{17}$$

Exercise Generate some random matrix in MATLAB and to show an example of the above.

3.1 Power method

```

import numpy as np
# create left stochastic matrix
d = 4
K = np.random.rand(d,d)
print(K.sum(axis=0) [None,:])
K = K/(K.sum(axis=0) [None,:])
print(K)
print("")

```

```

# K_\infty = K^100
Kinf = np.linalg.matrix_power(K, 100)
print(Kinf)

# try a random initialization
print("random initialization")
for i in range(10):
    pi = np.random.rand(d, 1)
    pi = pi/sum(pi)
    print("")
    print(Kinf@pi)

```

We will see the same power method in Page Ranking algorithm again. The initial probability vector: $\pi^{(1)}$ can be expressed as a linear combination of eigenvectors of K :

$$\pi^{(1)} = c_1 \times \pi^* + c_2 v_2 + \dots c_n v_n \quad (18)$$

Then:

$$\begin{aligned}
K\pi^{(1)} &= K(\pi^* + c_2 v_2 + \dots c_n v_n) \\
&= c_1 \underbrace{\lambda_1}_{=1} \pi^* + c_2 \lambda_2 v_2 + \dots c_n \lambda_n v_n \quad \text{definition of eigen value/vector} \\
&= c_1 \pi^* + c_2 \lambda_2 v_2 + \dots c_n \lambda_n v_n \\
\Rightarrow K^2 x &= c_1 \pi^* + c_2 \lambda_2^2 v_2 + \dots c_n \lambda_n^2 v_n \\
\Rightarrow K^t x &= c_1 \pi^* + c_t \lambda_2^t v_2 + \dots c_n \lambda_n^t v_n
\end{aligned} \quad (19)$$

therefore:

$$\begin{aligned}
&\lim_{t \rightarrow \infty} \lambda_j^k \rightarrow 0 \\
\Rightarrow \lim_{t \rightarrow \infty} K^t x &\rightarrow c_1 \pi^*
\end{aligned} \quad (20)$$

and since $K^t x$ will result a stochastic vector, so $c_1 \rightarrow 1$

3.2 Extend to continous case

in the **discrete** case:

$$\begin{bmatrix} K_{1 \rightarrow 1} & K_{2 \rightarrow 1} & \dots & K_{n \rightarrow 1} \\ \dots & \dots & \dots & \dots \\ K_{1 \rightarrow d} & K_{2 \rightarrow d} & \dots & K_{n \rightarrow d} \\ \dots & \dots & \dots & \dots \\ K_{1 \rightarrow n} & K_{2 \rightarrow n} & \dots & K_{n \rightarrow n} \end{bmatrix} \begin{bmatrix} \pi_1^* \\ \dots \\ \pi_d^* \\ \dots \\ \pi_n^* \end{bmatrix} = \begin{bmatrix} \pi_1^* \\ \dots \\ \pi_d^* \\ \dots \\ \pi_n^* \end{bmatrix} \quad (21)$$

then let's see what it may be in the **continuous** case, let $\pi(x)$ be the target distribution:

$$\pi(x^{(n+1)}) = \int_{x_n} \pi(x^{(n)}) K(x^{(n)} \rightarrow x^{(n+1)}) \quad (22)$$

A transition kernel K contains element-wise entries:

$$\{K(x^{(n)} \rightarrow x^{(n+1)})\} \quad \forall x^{(n)}, x^{(n+1)} \quad (23)$$

Sometimes we prefer to write $(x^{(n)})$ as x and $(x^{(n+1)})$ as x^*

- $K(x \rightarrow x^*)$ is the probability a process at state x moves to state x^* in a **one step**
- $K^n(x \rightarrow x^*)$ is the probability a process at state x moves to state x^* in **n steps**

3.2.1 Power Method Convergence in continuous case

One may have first sample $x^{(1)}$ distributed from an arbitrary distribution:

$$x^{(1)} \sim \pi^{(1)} \quad (24)$$

by applying K function, to obtain $x^{(2)}$ given $x^{(1)}$ with probability:

$$\begin{aligned} \pi^{(2)}(x^{(2)}) &= \int_{x^{(1)}} \pi(x^{(1)}, x^{(2)}) dx^{(1)} \\ &= \int_{x^{(1)}} \pi^{(1)}(x^{(1)}) K(x^{(1)} \rightarrow x^{(2)}) dx^{(1)} \end{aligned} \quad (25)$$

by applying K function again, to obtain $x^{(3)}$ with probability:

$$\begin{aligned} \pi^{(3)}(x^{(3)}) &= \int_{x^{(1)}} \int_{x^{(2)}} \pi(x^{(1)}, x^{(2)}, x^{(3)}) dx^{(1)} dx^{(2)} \\ &= \int_{x^{(1)}} \int_{x^{(2)}} \pi^{(1)}(x^{(1)}) K(x^{(1)} \rightarrow x^{(2)}) K(x^{(2)} \rightarrow x^{(3)}) dx^{(1)} dx^{(2)} \quad \text{Markov} \\ &= \int_{x^{(1)}} \pi^{(1)}(x^{(1)}) \underbrace{\int_{x^{(2)}} K(x^{(1)} \rightarrow x^{(2)}) K(x^{(2)} \rightarrow x^{(3)}) dx^{(2)}}_{K^2(x^{(1)} \rightarrow x^{(3)})} dx^{(1)} \\ &= \int_{x^{(1)}} \pi^{(1)}(x^{(1)}) K^2(x^{(1)} \rightarrow x^{(3)}) dx^{(1)} \\ &\vdots \\ \pi^{(t)}(x^{(t)}) &= \int_{x^{(1)}} \pi^{(1)}(x^{(1)}) K^{t-1}(x^{(1)} \rightarrow x^{(t)}) dx^{(1)} \end{aligned} \quad (26)$$

The last line is simply the continuous (or function equivalent) of $\pi^{(t)} = K\pi^{(t-1)}$. Then:

$$\lim_{t \rightarrow \infty} \pi^{(t)}(x^{(t)}) \rightarrow \pi(x^{(t)}) \quad (27)$$

3.3 MCMC algorithm

Given the above formula, it seems that we can (using the correct/corresponding kernel $K(x \rightarrow x^*)$ to construct a series of distributions $\pi^{(1)}, \pi^{(2)}, \dots$, and eventually, it will converge to a stationary distributions π . Along the way, we can sample from these distributions. However, this does not help at all! All the construction of auxiliary distributions $\pi^{(1)}, \pi^{(2)}, \dots$ are of no interest to us at all!

Instead, however, we can conditionally transit (or informally “move”) one sample using conditional density/transition kernel $K(x \rightarrow x^*)$, and as Eq.(26) shows that at time t^{th} of the “movement”, the samples will be targeting $\pi^{(t)}$. Therefore, as long as we keep “move” them enough times, they eventually will be targeting the stationary distribution π , and thereafter, applying $K(x \rightarrow x^*)$ again won’t change its distribution.

3.4 Burn in samples

We know,

$$\lim_{t \rightarrow \infty} \pi^{(t)}(x^{(t)}) \rightarrow \pi(x^{(t)}) \quad (28)$$

But, in practice,

$$\lim_{t \rightarrow B} \pi^{(t)}(x^{(t)}) \not\rightarrow \pi(x^{(t)}) \quad (29)$$

$\{x^{(1)}, \dots, x^{(B)}\}$ are the **burn-in** samples, which we discard.

3.5 What is MCMC research is all about

- **equilibrium equation:**

$$\pi(x^*) = \int_x \pi(x) K(x \rightarrow x^*) dx \quad (30)$$

- In machine learning, we always know the expression of stationary distribution $\pi(x)$,
- Our task is therefore, given target distribution $\pi(x)$, find the **corresponding** $K(x \rightarrow x^*)$ to generate samples in a Markov fashion.

3.6 Detailed Balance

At equilibrium, that stationary distribution satisfies:

$$\pi(x^*) = \int_x \pi(x)K(x \rightarrow x^*)dx \quad \text{equilibrium equation} \quad (31)$$

Proving **equilibrium equation** may be difficult in some cases, therefore, we instead prove **detailed balance**:

$$\pi(x)K(x \rightarrow x^*) = \pi(x^*)K(x^* \rightarrow x) \quad (32)$$

detailed balance implies **equilibrium equation**:

$$\begin{aligned} \int_x \pi(x)K(x \rightarrow x^*)dx &= \int_x \pi(x^*)K(x^* \rightarrow x)dx \\ &= \pi(x^*) \int_x K(x^* \rightarrow x)dx \\ &= \pi(x^*) \quad \text{equilibrium equation} \end{aligned} \quad (33)$$

the reverse is not always true.

3.7 Extend target distribution with auxiliary variables

- At equilibrium, that stationary distribution satisfies:

$$\pi(x^*) = \int_x \pi(x)K(x \rightarrow x^*)dx \quad (34)$$

- under many scenarios, we may have an extended joint density (x, u) :

$$\pi(x|u)\pi(u)K(u, x \rightarrow u^*, x^*) = \pi(x^*|u^*)\pi(u^*)K(x^*, u^* \rightarrow x, u) \quad (35)$$

- u is auxiliary variables help sampling
- one needs to ensure that:

$$\int_u \pi(x, u)du = \pi(x) \quad (36)$$

3.8 Alternative Use of Stochastic Matrix

- Before dive deep into MCMC algorithms, let's have a look at alternative use of stochastic matrix
- PageRank algorithm is different to MCMC, in PageRank algorithm: K is known
- PageRank algorithm then computes π which is the **invariant distribution**, tells the importance of each web page.

4 PageRank algorithm (Optional)

This is the opposite problem to monte-carlo markov chain. In MCMC, we do know target distribution π , but we need to discover the transition Kernel K , so that we can put it in a conditional density algorithm. However, for Page rank algorithm, we do know transition Kernel K , but we do not know what is the target distribution π

Imagine we have the following four web pages and their links, we can then compute the probability of navigating from i^{th} page (discrete state) to j^{th} page (discrete state)

- Page 1 links to pages $\{2, 3\}$

$$\implies K_{1 \rightarrow 1} = 0, K_{1 \rightarrow 2} = \frac{1}{2}, K_{1 \rightarrow 3} = \frac{1}{2}, K_{1 \rightarrow 4} = 0 \quad (37)$$

- Page 2 has links to pages $\{1, 3, 4\}$

$$\implies K_{2 \rightarrow 1} = \frac{1}{3}, K_{2 \rightarrow 2} = 0, K_{2 \rightarrow 3} = \frac{1}{3}, K_{2 \rightarrow 4} = \frac{1}{3} \quad (38)$$

- Page 3 has links to pages $\{1, 3\}$

$$\implies K_{3 \rightarrow 1} = \frac{1}{2}, K_{3 \rightarrow 2} = 0, K_{3 \rightarrow 3} = \frac{1}{2}, K_{3 \rightarrow 4} = 0 \quad (39)$$

- Page 4 has links to pages $\{2, 3\}$

$$\implies K_{4 \rightarrow 1} = 0, K_{4 \rightarrow 2} = \frac{1}{2}, K_{4 \rightarrow 3} = \frac{1}{2}, K_{4 \rightarrow 4} = 0 \quad (40)$$

4.1 Stochastic matrix K

- From the preceding example, **Left stochastic matrix** is:

$$\begin{bmatrix} K_{1 \rightarrow 1} & K_{1 \rightarrow 2} & K_{1 \rightarrow 3} & K_{1 \rightarrow 4} \\ K_{2 \rightarrow 1} & K_{2 \rightarrow 2} & K_{2 \rightarrow 3} & K_{2 \rightarrow 4} \\ K_{3 \rightarrow 1} & K_{3 \rightarrow 2} & K_{3 \rightarrow 3} & K_{3 \rightarrow 4} \\ K_{4 \rightarrow 1} & K_{4 \rightarrow 2} & K_{4 \rightarrow 3} & K_{4 \rightarrow 4} \end{bmatrix} = \begin{bmatrix} 0 & \frac{1}{2} & \frac{1}{2} & 0 \\ \frac{1}{3} & 0 & \frac{1}{3} & \frac{1}{3} \\ \frac{1}{2} & 0 & \frac{1}{2} & 0 \\ 0 & \frac{1}{2} & \frac{1}{2} & 0 \end{bmatrix} \quad (41)$$

- From Power Method Convergence Theorem, we know:

- sequence $\{\pi^{(1)}, K\pi^{(1)}, K^2\pi^{(1)}, \dots, K^t\pi^{(1)}, \dots, K^\infty\pi^{(1)}\}$ converges to the vector π^*

$$\lim_{t \rightarrow \infty} K^t \pi^{(1)} = \pi^* \quad (42)$$

where π^* is a **probabilistic eigenvector** of K corresponding to the eigenvalue 1.

- **Exercise** What is the usefulness of π^* in the setting of web pages?

4.2 Usefulness of π^* in the setting of web pages

The **answer** to usefulness of π^* in the setting of web pages is:

- Shows how **important** each webpage is
- i.e., regardless of the probabilities of the initial webpage visit: $\pi^{(1)}$,
- $\pi^{(1)} \rightarrow \pi^*$, where $\pi^*(i)$ is the target distribution i.e, the probability that the visit will end up at a web page i .
- Note that this is a **reverse problem** of MCMC

4.3 Dangling nodes

- What happens when you have the following K :

$$\begin{bmatrix} K_{1 \rightarrow 1} & K_{2 \rightarrow 1} & K_{3 \rightarrow 1} & K_{4 \rightarrow 1} \\ K_{1 \rightarrow 2} & K_{2 \rightarrow 2} & K_{3 \rightarrow 2} & K_{4 \rightarrow 2} \\ K_{1 \rightarrow 3} & K_{2 \rightarrow 3} & K_{3 \rightarrow 3} & K_{4 \rightarrow 3} \\ K_{1 \rightarrow 4} & K_{2 \rightarrow 4} & K_{3 \rightarrow 4} & K_{4 \rightarrow 4} \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & \frac{1}{2} & 0 & 0 \\ \frac{1}{2} & 0 & 0 & 0 \\ \frac{1}{2} & \frac{1}{2} & 1 & 0 \end{bmatrix} \quad (43)$$

- Note that 4th has no out-going node
- [Exercise check eigenvector correspond to eigenvalue of 1](#)
- What is the eigenvector correspond to eigenvalue of 1, if we change K into:

$$\begin{bmatrix} K_{1 \rightarrow 1} & K_{2 \rightarrow 1} & K_{3 \rightarrow 1} & K_{4 \rightarrow 1} \\ K_{1 \rightarrow 2} & K_{2 \rightarrow 2} & K_{3 \rightarrow 2} & K_{4 \rightarrow 2} \\ K_{1 \rightarrow 3} & K_{2 \rightarrow 3} & K_{3 \rightarrow 3} & K_{4 \rightarrow 3} \\ K_{1 \rightarrow 4} & K_{2 \rightarrow 4} & K_{3 \rightarrow 4} & K_{4 \rightarrow 4} \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & \frac{1}{2} & 0 & 0 \\ \frac{1}{2} & 0 & 0 & 0 \\ \frac{1}{2} & \frac{1}{2} & 1 & \mathbf{1} \end{bmatrix} \quad (44)$$

[Exercise give reason to why this is so?](#)

- [Exercise How can we solve this?](#)

4.4 Dangling nodes: what may be the solution?

$$\begin{bmatrix} K_{1 \rightarrow 1} & K_{2 \rightarrow 1} & K_{3 \rightarrow 1} & K_{4 \rightarrow 1} \\ K_{1 \rightarrow 2} & K_{2 \rightarrow 2} & K_{3 \rightarrow 2} & K_{4 \rightarrow 2} \\ K_{1 \rightarrow 3} & K_{2 \rightarrow 3} & K_{3 \rightarrow 3} & K_{4 \rightarrow 3} \\ K_{1 \rightarrow 4} & K_{2 \rightarrow 4} & K_{3 \rightarrow 4} & K_{4 \rightarrow 4} \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & \frac{1}{2} & 0 & 0 \\ \frac{1}{2} & 0 & 0 & 0 \\ \frac{1}{2} & \frac{1}{2} & 1 & 0 \end{bmatrix} \quad (45)$$

- One simply solution is:

$$\begin{bmatrix} K_{1 \rightarrow 1} & K_{2 \rightarrow 1} & K_{3 \rightarrow 1} & K_{4 \rightarrow 1} \\ K_{1 \rightarrow 2} & K_{2 \rightarrow 2} & K_{3 \rightarrow 2} & K_{4 \rightarrow 2} \\ K_{1 \rightarrow 3} & K_{2 \rightarrow 3} & K_{3 \rightarrow 3} & K_{4 \rightarrow 3} \\ K_{1 \rightarrow 4} & K_{2 \rightarrow 4} & K_{3 \rightarrow 4} & K_{4 \rightarrow 4} \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 & \frac{1}{3} \\ 0 & \frac{1}{2} & 0 & \frac{1}{3} \\ \frac{1}{2} & 0 & 0 & \frac{1}{3} \\ \frac{1}{2} & \frac{1}{2} & 1 & 0 \end{bmatrix} \quad (46)$$

- in words, it means any page doesn't have out-link, we assume it has equal probability of visiting entire web.
- Of course, **data mining** researchers may argue certain web page (having certain properties) may attract higher weights etc.

4.5 Disconnected sub-graphs

- What happens when you have the following K :

$$\begin{bmatrix} K_{1 \rightarrow 1} & K_{2 \rightarrow 1} & K_{3 \rightarrow 1} & K_{4 \rightarrow 1} \\ K_{1 \rightarrow 2} & K_{2 \rightarrow 2} & K_{3 \rightarrow 2} & K_{4 \rightarrow 2} \\ K_{1 \rightarrow 3} & K_{2 \rightarrow 3} & K_{3 \rightarrow 3} & K_{4 \rightarrow 3} \\ K_{1 \rightarrow 4} & K_{2 \rightarrow 4} & K_{3 \rightarrow 4} & K_{4 \rightarrow 4} \end{bmatrix} = \begin{bmatrix} \frac{1}{2} & 0 & 0 & 0 \\ \frac{1}{2} & 1 & 0 & 0 \\ 0 & 0 & 0 & \frac{1}{2} \\ 0 & 0 & 1 & \frac{1}{2} \end{bmatrix} \quad (47)$$

- node $\{1, 2\}$ and $\{3, 4\}$ each form a sub-graph.
- **Exercise** check eigenvector correspond to eigenvalue of 1, also multiplicity of eigenvalue 1
- **Exercise** How can we solve this?

4.6 Disconnected sub-graphs: what may be the solution?

$$\begin{bmatrix} K_{1 \rightarrow 1} & K_{2 \rightarrow 1} & K_{3 \rightarrow 1} & K_{4 \rightarrow 1} \\ K_{1 \rightarrow 2} & K_{2 \rightarrow 2} & K_{3 \rightarrow 2} & K_{4 \rightarrow 2} \\ K_{1 \rightarrow 3} & K_{2 \rightarrow 3} & K_{3 \rightarrow 3} & K_{4 \rightarrow 3} \\ K_{1 \rightarrow 4} & K_{2 \rightarrow 4} & K_{3 \rightarrow 4} & K_{4 \rightarrow 4} \end{bmatrix} = \begin{bmatrix} \frac{1}{2} & 0 & 0 & 0 \\ \frac{1}{2} & 1 & 0 & 0 \\ 0 & 0 & 0 & \frac{1}{2} \\ 0 & 0 & 1 & \frac{1}{2} \end{bmatrix} \quad (48)$$

- One solution is to use a convex combination between K and a square matrix having identical elements $\frac{1}{n}$:

$$K' = (1 - p)K + p \left(\frac{1}{n} \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \end{bmatrix} \right) \quad (49)$$

- in words, it means most of the time $1 - p$, a surfer will follow links to navigate a page
- but with probability p , it will arbitrarily close the current page and go to the new one
- **Exercise** Prove K' remains a left stochastic matrix

4.7 How to compute the one hundblue billion dimension eigenvector?

- starting from the vector (not probabilistic eigenvector), x :

$$x = [1 \quad 1 \quad \dots \quad 1]^\top \quad (50)$$

- generate the sequence: $\{x, Kx, K^2x \dots K^tx\}$ until convergence then its is the eigenvectors of K correspond to eigenvalue of 1, up to a normalisation constant c
- This is solved using **power method**

4.8 Power method

power method is used to finding an eigenvector of a square matrix corresponding to the **largest** eigenvalue (in terms of absolute value). We already saw it in the section (3.1):

- for stochastic matrix K has eigenvalues:

$$1 = \lambda_1 > |\lambda_2| \geq |\lambda_3| \geq \dots \geq |\lambda_n| \quad (51)$$

- the initial vector: x as a linear combination of eigenvectors of K :

$$x = c_1 v_1 + c_2 v_2 + \dots c_n v_n \quad (52)$$

Then,

$$\begin{aligned} Kx &= K(c_1 v_1 + c_2 v_2 + \dots c_n v_n) \\ &= c_1 \underbrace{\lambda_1}_{=1} v_1 + c_2 \lambda_2 v_2 + \dots c_n \lambda_n v_n \quad \text{definition of eigen value/vector} \\ &= c_1 v_1 + c_2 \lambda_2 v_2 + \dots c_n \lambda_n v_n \\ \implies K^2 x &= c_1 v_1 + c_2 \lambda_2^2 v_2 + \dots c_n \lambda_n^2 v_n \\ \implies K^t x &= c_1 v_1 + c_t \lambda_2^t v_2 + \dots c_n \lambda_n^t v_n \end{aligned} \quad (53)$$

$$\lambda_j^k \rightarrow 0 \text{ when } j \geq 2 \implies K^t x \rightarrow c_1 v_1 \quad (54)$$

4.9 Few notes

- The second largest eigen value determines the convergence
- **Exercise** Perform the following simulations:
 - generate lots of K and choose one which has **large** second eigen values in absolute value
 - also generate a K which has **small** second eigen values in absolute value

- in both cases, try to compute the sequence $\{x, Kx, K^2x \dots K^t x\}$, using an arbitrary vector x
- **Exercise** Generate K from known eigen value/vectors are called Inverse Eigen-value Problems. Use IEP to generate stochastic matrices above
- Try something like, “Doubly Stochastic Matrices with Prescribed Positive Spectrum”

5 Metropolis Hasting Algorithm

Let's take a look at the M.H. Algorithm:

1. initialize $x^{(0)}$
2. run:

$$\begin{aligned}
 &\textbf{for } i = 0 \text{ to } N - 1 \\
 &\quad u \sim U(0, 1) \\
 &\quad x^* \sim q(x^* | x^{(i)}) \\
 &\quad \textbf{if } u < \min \left(1, \frac{\pi(x^*)q(x | x^*)}{\pi(x)q(x^* | x)} \right) \\
 &\quad \quad x^{(i+1)} = x^* \\
 &\quad \textbf{else} \\
 &\quad \quad x^{(i+1)} = x^{(i)}
 \end{aligned} \tag{55}$$

The key message here is that it does not "drop" samples like rejection sampling. It just "duplicates" the sample. If the same sample is repeated too many times, it has **bad mixing**

see demo for an example.

5.1 Metropolis Hasting - Why it work?

$K(x \rightarrow x^*)$ includes the joint density of the following:

1. Propose x^* from $q(x^* | x)$,
2. then accept x^* with ratio:

$$\alpha(x^*, x) = \min \left(1, \frac{\pi(x^*)q(x | x^*)}{\pi(x)q(x^* | x)} \right) \tag{56}$$

very easily verify it satisfy **detailed balance**:

$$\begin{aligned}
 \pi(x)q(x^* | x)\alpha(x^*, x) &= \pi(x)q(x^* | x) \min \left(1, \frac{\pi(x^*)q(x | x^*)}{\pi(x)q(x^* | x)} \right) \\
 &= \min \left(\pi(x)q(x^* | x), \pi(x^*)q(x | x^*) \right) \\
 &= \pi(x^*)q(x | x^*) \min \left(1, \frac{\pi(x)q(x^* | x)}{\pi(x^*)q(x | x^*)} \right) \\
 &= \pi(x^*)q(x | x^*)\alpha(x, x^*)
 \end{aligned} \tag{57}$$

note that $\alpha(x^*, x) \neq \alpha(x, x^*)!$

Exercise wait a second, are we missing anything here?

5.2 Metropolis Hasting - Missing the self transition part

1. Case 1: $x^* \neq x$

$$K(x \rightarrow x^*) = \alpha(x^*, x)q(x^*|x) \quad (58)$$

detailed balance was already seen in Eq.(57)

2. Case 2: $x^* = x$

$$K(x \rightarrow x) = \alpha(x, x)q(x|x) + \int_{x'} q(x'|x)(1 - \alpha(x', x))dx' \quad (59)$$

detailed balance is **trivially** seen, as this is totally symmetrical

5.2.1 something to think about

let $\pi(x) \propto L(x)\pi_{\text{prior}}(x)$:

$$\begin{aligned} \alpha(x^*, x) &= \min \left(1, \frac{\pi(x^*)q(x|x^*)}{\pi(x)q(x^*|x)} \right) \\ \implies \alpha(x^*, x) &= \min \left(1, \underbrace{\frac{\pi_{\text{prior}}(x^*)q(x|x^*)}{\pi_{\text{prior}}(x)q(x^*|x)}}_{\text{may be cheaper to compute}} \right) \min \left(1, \frac{L(x^*)}{L(x)} \right) \end{aligned} \quad (60)$$

what if $q(x^*|x)$ is symmetrical, like Gaussian, i.e., $q(x^*|x) = q(x|x^*)$

5.3 Gibbs sampling

you would like to use Gibbs sampling algorithm to sample:

$$\{(x_1, y_1, z_1)^\top, (x_2, y_2, z_2)^\top, (x_3, y_3, z_3)^\top, \dots, (x_N, y_N, z_N)^\top\} \sim P(x, y, z) \quad (61)$$

the Gibbs sampling algorithm is:

1. starting with a sample $(x_1, y_1, z_1)^\top$
2. the algorithm is:

$$\begin{aligned}
x_2 &\sim P(x|y_1, z_1) \\
y_2 &\sim P(y|x_2, z_1) \\
z_2 &\sim P(z|x_2, y_2) \\
\hline
x_3 &\sim P(x|y_2, z_2) \\
y_3 &\sim P(y|x_3, z_2) \\
z_3 &\sim P(z|x_3, y_3) \\
&\vdots
\end{aligned} \tag{62}$$

5.4 Gibbs sampling Toy Example

In this toy example, let's sample:

$$\mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \sim \mathcal{N} \left(\begin{bmatrix} \mu_1 \\ \mu_2 \end{bmatrix}, \begin{bmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix} \right) \tag{63}$$

$$\begin{aligned}
x_1|x_2 &\sim \mathcal{N}(\mu_1 + \Sigma_{12}\Sigma_{22}^{-1}(x_2 - \mu_2), \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21}) \\
x_2|x_1 &\sim \mathcal{N}(\mu_2 + \Sigma_{12}\Sigma_{11}^{-1}(x_1 - \mu_1), \Sigma_{22} - \Sigma_{12}\Sigma_{11}^{-1}\Sigma_{12})
\end{aligned} \tag{64}$$

You can find Gaussian conditional

5.5 As a special case of M-H

Looking at the M-H acceptance ratio Let $\mathbf{x} = x_1, \dots, x_D$.

When sampling k^{th} component:

$$\begin{aligned}
q_k(\mathbf{x}^*|\mathbf{x}) &= \pi(x_k^*|\mathbf{x}_{-k}) \\
\mathbf{x}_{-k}^* &= \mathbf{x}_{-k}
\end{aligned} \tag{65}$$

let's take a look at the $\alpha(\mathbf{x}^*, \mathbf{x})$:

$$\frac{\pi(\mathbf{x}^*)q(\mathbf{x}|\mathbf{x}^*)}{\pi(\mathbf{x})q(\mathbf{x}^*|\mathbf{x})} = \frac{\pi(\mathbf{x}^*)\pi(x_k|\mathbf{x}_{-k}^*)}{\pi(\mathbf{x})\pi(x_k^*|\mathbf{x}_{-k})} = \frac{\pi(x_k^*|\mathbf{x}_{-k}^*)\pi(x_k|\mathbf{x}_{-k}^*)}{\pi(x_k|\mathbf{x}_{-k})\pi(x_k^*|\mathbf{x}_{-k})} = 1 \tag{66}$$

5.6 Collapsed Gibbs sampling

Treats (x, y) as a single variable

$$\begin{array}{l}
(x_2, y_2) \sim P(x, y|z_1) \quad \implies \quad x_2 \sim p(x|z_1) \quad y_2 \sim p(y|x_2, z_1) \\
z_2 \sim P(z|x_2, y_2) \\
\hline
(x_3, y_3) \sim P(x, y|z_2) \quad \implies \quad x_3 \sim p(x|z_2) \quad y_3 \sim p(y|x_3, z_2) \\
z_3 \sim P(z|x_3, y_3) \\
\vdots
\end{array} \tag{67}$$

However, we need to know how to compute:

$$P(x|z) = \int_y P(x, y|z) dy \tag{68}$$

The algorithm blueuces **auto-correction**.

5.7 What is auto-correction

- lag-k **autocovariance** of the functional $g(X_1), g(X_2)$

$$\gamma(k) = \text{cov}(g(X_i), g(X_{i+k})) \tag{69}$$

- lag-k **autocorrelation** of the functional $g(X_1), g(X_2)$

$$\frac{\gamma(k)}{\gamma(0)} \tag{70}$$

- need to perform **thinning** to make samples more like drawn using i.i.d
- Let's look at an autocorrelation **demo** for computing multivariate Gaussian distribution of having 2-D, ... 5-D.
- **Exercise** what would be an appropriate $g(\cdot)$ used here?
- **Exercise** you need to write a similar code

5.8 Parallel Gibbs sampling

- You can see the algorithm won't "parallelise".
- However, under some models (and clever work-around) machine learning researcher able to parallelise some Gibbs sampling scheme for various models, typically, using

$$p(x_1, x_2, \dots, x_n) = \int_u p(x_1, x_2, \dots, x_n|u)p(u)du \tag{71}$$

and also have the property that:

$$p(x_1, x_2, \dots, x_n | u) = \prod_{i=1}^n p(x_i | u) \quad (72)$$

- Well, make sense to perform inference to **Big data** with CUDA, multiple processors.

5.9 Convergence Diagnostics

- The question is when to stop sampling.
- **word of caution:** individual sample do not converge. It's the entire distribution.
- sample will generally be correlated with each other, slowing the algorithm in its attempt to sample from the entire stationary distribution
- run **convergence diagnostics:** *Cowles, M.K.; Carlin, B.P. (1996). "Markov chain Monte Carlo convergence diagnostics: a comparative review". Journal of the American Statistical Association. 91: 883 - 904.*
- or using R Package "coda"

6 Gibbs sampling for Latent Dirichlet Allocation

Remember the graphical model for Latent Dirichlet Allocation [1]?

$$\begin{aligned}
 &\beta_k \sim \text{Dir}(\eta, \dots, \eta) \quad \text{for } k \in \{1, \dots, K\} \\
 &\text{for each doc } d : \\
 &\quad \theta \sim \text{Dir}(\alpha, \dots, \alpha) \\
 &\quad \text{for each word } w \in \{1, \dots, d_N\} : \\
 &\quad \quad z_{dn} \sim \text{Mult}(\theta_d) \\
 &\quad \quad w_{dn} \sim \text{Mult}(\beta_{z_{dn}})
 \end{aligned} \tag{73}$$

our goal is to sample:

$$p(\{\beta_j\}_{j=1}^K, \{\theta_d\}_{d=1}^D, \{z_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\} | \{w_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\}) \tag{74}$$

let's see how this can be done by Gibbs sampling

6.1 Basic tools: Multinomial-Dirichlet

Posterior

$$\begin{aligned}
 &P(p_1, \dots, p_k | n_1, \dots, n_k) \\
 &\propto \underbrace{\frac{\Gamma(\sum_{i=1}^k \alpha_i)}{\prod_{i=1}^k \Gamma(\alpha_i)} \prod_{i=1}^k p_i^{\alpha_i - 1}}_{\text{Dir}(p_1, \dots, p_k | \alpha_1, \dots, \alpha_k)} \underbrace{\frac{n!}{n_1! \dots n_k!} \prod_{i=1}^k p_i^{n_i}}_{\text{Mult}(n_1, \dots, n_k | p_1, \dots, p_k)} \\
 &\propto \prod_{i=1}^k p_i^{\alpha_i - 1} \prod_{i=1}^k p_i^{n_i} = \prod_{i=1}^k p_i^{\alpha_i - 1 + n_i} \\
 &= \text{Dir}(p_1, \dots, p_k | \alpha_i + n_i, \dots, \alpha_k + n_k)
 \end{aligned} \tag{75}$$

Marginal

$$\begin{aligned}
p(n_1, \dots, n_k) &= \int_{p_1, \dots, p_k} P(p_1, \dots, p_k, n_1, \dots, n_k) \\
&= \frac{\Gamma\left(\sum_{i=1}^k \alpha_i\right)}{\prod_{i=1}^k \Gamma(\alpha_i)} \frac{n!}{n_1! \dots n_k!} \int_{p_1, \dots, p_k} \prod_{i=1}^k p_i^{\alpha_i - 1 + n_i} \\
&= \frac{N!}{n_1! \dots n_k!} \times \frac{\Gamma\left(\sum_{i=1}^k \alpha_i\right)}{\prod_{i=1}^k \Gamma(\alpha_i)} \times \frac{\prod_{i=1}^k \Gamma(\alpha_i + n_i)}{\Gamma\left(N + \sum_{i=1}^k \alpha_i\right)}
\end{aligned} \tag{76}$$

6.2 Gibbs sampling for Latent Dirichlet Allocation

The parameters of the model include:

- $\{\beta_k\}_{k=1}^K$ each β_k has dimension V (vocab)
- $\{\theta_d\}_{d=1}^D$
- $\{z_{d \in \{1, \dots, D\}}, n \in \{1, \dots, d_N\}\}$

since everything **conjugate**, posterior inference is easy:

1. for each topic k :

$$\beta_k \sim \text{Dir}(\eta + N_1^{(k)}, \dots, \eta + N_v^{(k)}, \eta + N_V^{(k)}) \quad k \in \{1, \dots, K\} \tag{77}$$

where $N_v^{(k)} = \#(\{w_{dn} = v \text{ AND } z_{dn} = k\})$; In words, this means the number of times the v^{th} word is assigned to the topic k in the entire document corpus:

Let's illustrate this with a scenario where the vocabulary size is $V = 3$ and the number of topics $K = 3$:

d_1	d_2
$(w_{1,1} = 1, z_{1,1} = 1)$	$(w_{2,1} = 2, z_{2,1} = 2)$
$(w_{1,2} = 2, z_{1,2} = 2)$	$(w_{2,2} = 2, z_{2,2} = 2)$
$(w_{1,3} = 2, z_{1,3} = 3)$	$(w_{2,3} = 3, z_{2,3} = 1)$
$(w_{1,4} = 1, z_{1,4} = 1)$	$(w_{2,4} = 3, z_{2,4} = 1)$
$(w_{1,5} = 3, z_{1,5} = 3)$	$(w_{2,5} = 1, z_{2,5} = 3)$
$(w_{1,6} = 2, z_{1,6} = 2)$	$(w_{2,6} = 2, z_{2,6} = 3)$
$(w_{1,7} = 1, z_{1,7} = 2)$	$(w_{2,7} = 1, z_{2,7} = 1)$

let's illustrate just with one example of how to compute $N_2^{(3)}$:

- (a) firstly, let's find elements where $v = 2$, i.e, those entries with $w_{i,j} = 2$:

d_1	d_2
$(w_{1,1} = 1, z_{1,1} = 1)$	$(w_{2,1} = 2, z_{2,1} = 2)$
$(w_{1,2} = 2, z_{1,2} = 2)$	$(w_{2,2} = 2, z_{2,2} = 2)$
$(w_{1,3} = 2, z_{1,3} = 3)$	$(w_{2,3} = 3, z_{2,3} = 1)$
$(w_{1,4} = 1, z_{1,4} = 1)$	$(w_{2,4} = 3, z_{2,4} = 1)$
$(w_{1,5} = 3, z_{1,5} = 3)$	$(w_{2,5} = 1, z_{2,5} = 3)$
$(w_{1,6} = 2, z_{1,6} = 2)$	$(w_{2,6} = 2, z_{2,6} = 3)$
$(w_{1,7} = 1, z_{1,7} = 2)$	$(w_{2,7} = 1, z_{2,7} = 1)$

(b) then, you see that there are 2 times for $z_{i,j} = 3$:

d_1	d_2
$(w_{1,1} = 1, z_{1,1} = 1)$	$(w_{2,1} = 2, z_{2,1} = 2)$
$(w_{1,2} = 2, z_{1,2} = 2)$	$(w_{2,2} = 2, z_{2,2} = 2)$
$(w_{1,3} = 2, z_{1,3} = 3)$	$(w_{2,3} = 3, z_{2,3} = 1)$
$(w_{1,4} = 1, z_{1,4} = 1)$	$(w_{2,4} = 3, z_{2,4} = 1)$
$(w_{1,5} = 3, z_{1,5} = 3)$	$(w_{2,5} = 1, z_{2,5} = 3)$
$(w_{1,6} = 2, z_{1,6} = 2)$	$(w_{2,6} = 2, z_{2,6} = 3)$
$(w_{1,7} = 1, z_{1,7} = 2)$	$(w_{2,7} = 1, z_{2,7} = 1)$

then we have:

$$N_2^{(3)} = 2 \tag{78}$$

2. For each document d :

$$\theta_d \sim \text{Dir}(\alpha + M_1^{(d)}, \dots, \alpha + M_K^{(d)}) \tag{79}$$

where $M_k^{(d)} = \#\{z_{d,n} = k\}$

this can be illustrated using the following table of updating θ_1 from d_1 :

d_1
$(w_{1,1} = 1, z_{1,1} = 1)$
$(w_{1,2} = 2, z_{1,2} = 2)$
$(w_{1,3} = 2, z_{1,3} = 3)$
$(w_{1,4} = 1, z_{1,4} = 1)$
$(w_{1,5} = 3, z_{1,5} = 3)$
$(w_{1,6} = 2, z_{1,6} = 2)$
$(w_{1,7} = 1, z_{1,7} = 2)$

we can tell that $M_1^{(1)} = 2, M_2^{(1)} = 3, M_3^{(1)} = 1$

For each word $z_{dn} \in \{1, \dots, d_N\} \quad \forall d \in \{1, \dots, D\}$:

$$\begin{aligned} \Pr(z_{dn} = \textcolor{red}{k}) &= \Pr(w_{dn} | z_{dn} = \textcolor{red}{k}, \beta_k) p(z_{dn} = \textcolor{red}{k} | \theta_d) \\ &\propto \beta_{k, w_{dn}} \theta_{d,k} \end{aligned} \tag{80}$$

6.2.1 looking at Gibbs for LDA more closely

For the Gibbs sampling of each of the set of variables:

1. the first line is condition on ALL rest of the variables
2. the second line is condition only on the Markov Blanket. You need to spend some time to think about why this is so in each case
3. the last line is the actual formula

$$\begin{aligned}
p(\beta_k | \{\beta_j\}_{j=1, j \neq k}^K, \{\theta_d\}_{d=1}^D, \{z_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\}, \{w_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\}) \\
= p(\beta_k | \{\theta_d\}_{d=1}^D, \{z_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\}, \{w_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\}) \\
= \text{Dir}(\eta + N_1^{(k)}, \dots, \eta + N_V^{(k)})
\end{aligned} \tag{81}$$

$$\begin{aligned}
p(\theta_d | \{\beta_j\}_{j=1}^K, \{\theta_j\}_{j=1, j \neq d}^D, \{z_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\}, \{w_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\}) \\
= p(\theta_d | \{z_{d, n \in \{1 \dots N\}}\}) \\
= \text{Dir}(\alpha + M_1^{(d)}, \dots, \alpha + M_K^{(d)})
\end{aligned} \tag{82}$$

$$\begin{aligned}
p(z_{dn} = k | \{\beta_j\}_{j=1}^K, \{\theta_d\}_{d=1}^D, \{z_{d \in \{1 \dots D\}, j \in \{1 \dots N\}, j \neq n}\}, \{w_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\}) \\
= p(z_{dn} = k | \theta_d, w_{d, n}) \\
\propto \beta_{k, w_{dn}} \theta_{d, k}
\end{aligned} \tag{83}$$

6.3 Collapsed sampling for LDA (Optional)

- we may only interested in sampling $\{z_{d \in \{1 \dots D\}, n \in \{1 \dots N\}}\}$
- we could collapse both $\{\beta_j\}_{j=1, j \neq k}^K$ and $\{\theta_d\}_{d=1}^D$,

$$p(z_{dn} | \mathbf{z}_{-dn}, \mathbf{w}) \tag{84}$$

where \mathbf{z}_{-dn} are all the \mathbf{z} except z_{dn}

$$\begin{aligned}
\Pr(z_{dn} | \mathbf{z}_{-dn}, \mathbf{w}) \\
\propto \Pr(z_{dn}, \mathbf{z}_{-dn}, w_{dn}, \mathbf{w}_{-dn}) \\
= \Pr(w_{dn} | z_{dn}, \mathbf{z}_{-dn}, \mathbf{w}_{-dn}) \Pr(z_{dn}, \mathbf{z}_{-dn}, \mathbf{w}_{-dn}) \\
= \Pr(w_{dn} | z_{dn}, \mathbf{z}_{-dn}, \mathbf{w}_{-dn}) \Pr(z_{dn} | \mathbf{z}_{-dn}, \mathbf{w}_{-dn}) \Pr(\mathbf{z}_{-dn}, \mathbf{w}_{-dn}) \\
\propto \Pr(w_{dn} | z_{dn}, \mathbf{z}_{-dn}, \mathbf{w}_{-dn}) \underbrace{\Pr(z_{dn} | \mathbf{z}_{-dn})}_{\text{there is no } \mathbf{w}, \text{prior}}
\end{aligned} \tag{85}$$

- note that, previously, $\Pr(w_{dn} | z_{dn}, \mathbf{z}_{-dn}, \mathbf{w}_{-dn}, \beta) = \Pr(w_{dn} | z_{dn}, \beta_k) = \beta_{z_{dn}, w_{dn}}$

6.3.1 look at: $p(z_{dn} = i | \mathbf{z}_{-dn})$

$$\Pr(z_{dn} | \mathbf{z}_{-dn}, \mathbf{w}) \propto p(w_{dn} | z_{dn}, \mathbf{z}_{-dn}, \mathbf{w}_{-dn}) \underbrace{\Pr(z_{dn} | \mathbf{z}_{-dn})}_{(86)} \quad (86)$$

- Looking at $\Pr(z_{dn} = i | \mathbf{z}_{-dn})$ using i instead of loop index k :

$$\begin{aligned} \Pr(z_{dn} = i | \mathbf{z}_{-dn}) &= \int_{\theta_d} p(z_{dn} = i, \theta_d | \mathbf{z}_{-dn}) d\theta_d \\ &= \int_{\theta_d} \Pr(z_{dn} = i | \theta_d) p(\theta_d | \mathbf{z}_{-dn}) d\theta_d \\ &\propto \int_{\theta_d} \Pr(z_{dn} = i | \theta_d) \underbrace{\Pr(\mathbf{z}_{-dn} | \theta_d) p(\theta_d)}_{(86)} d\theta_d \\ &= \int_{\theta_d} \text{Mult}(z_{dn} = i | \theta_d) \underbrace{\text{Dir}(\alpha + N_1^{(d)}, \dots, \alpha + N_K^{(d)})}_{(86)} d\theta_d \\ &= \frac{\Gamma(\sum_{k=1}^K (\alpha + N_k^{(d)}))}{\prod_{k=1}^K \Gamma(\alpha + N_k^{(d)})} \times \frac{\Gamma((\alpha + N_i^{(d)}) + 1) \left(\prod_{k=1, k \neq i}^K \Gamma(\alpha + N_k^{(d)}) \right)}{\Gamma(1 + \sum_{k=1}^K (\alpha + N_k^{(d)}))} \\ &= \frac{\alpha + N_i^{(d)}}{\sum_{k=1}^K (\alpha + N_k^{(d)})} = \frac{\alpha + N_i^{(d)}}{K\alpha + N^{(d)}} \end{aligned} \quad (87)$$

- $N_i^{(d)}, N^{(d)}$ are counted without z_{dn} , i.e., $N_k^{(d)} = \#(\{z_{\widetilde{dn} \neq dn} = i\})$

6.3.2 look at: $p(w_{dn} | z_{dn} = i, \mathbf{z}_{-dn}, \mathbf{w}_{-dn})$

$$\Pr(z_{dn} | \mathbf{z}_{-dn}, \mathbf{w}) \propto \underbrace{p(w_{dn} | z_{dn} = i, \mathbf{z}_{-dn}, \mathbf{w}_{-dn})}_{(86)} \Pr(z_{dn} | \mathbf{z}_{-dn}) \quad (88)$$

- Looking at $\Pr(w_{dn} | z_{dn} = i, \mathbf{z}_{-dn}, \mathbf{w}_{-dn})$ using i instead of loop index k :

$$\begin{aligned} \Pr(w_{dn} | z_{dn} = i, \mathbf{z}_{-dn}, \mathbf{w}_{-dn}) &= \int_{\beta} \Pr(w_{dn}, \beta | z_{dn} = i, \mathbf{z}_{-dn}, \mathbf{w}_{-dn}) d\beta \\ &= \int_{\beta} \Pr(w_{dn} | \beta, z_{dn} = i, \mathbf{z}_{-dn}, \mathbf{w}_{-dn}) \underbrace{p(\beta, z_{dn} = i | \mathbf{z}_{-dn}, \mathbf{w}_{-dn})}_{(86)} p(\mathbf{z}_{-dn}, \mathbf{w}_{-dn}) d\beta \\ &\propto \int_{\beta_i} \Pr(w_{dn} | \beta, z_{dn} = i) \underbrace{p(\beta_i | \mathbf{z}_{-dn}, \mathbf{w}_{-dn})}_{(86)} d\beta_i \\ &= \int_{\beta_i} \beta_{i, w_{dn}} \underbrace{\text{Dir}(\eta + N_1^{(v)}, \dots, \eta + N_V^{(v)})}_{(86)} d\beta_i \end{aligned} \quad (89)$$

this is just the expectation of $\beta_{i, w_{dn}}$, i.e., the w_{dn}^{th} component of vector β_i

- using expectation of Dirichlet distribution:

$$\Pr(w_{dn}|z_{dn} = i, \mathbf{z}_{-dn}, \mathbf{w}_{-dn}) = \frac{\eta + N_{w_{dn}}^{(v)}}{\sum_{v \in \{1, \dots, V\}} \eta + N_{w_{dn}}^{(v)}} = \frac{\eta + N_{w_{dn}}^{(v)}}{V\eta + N^{(v)}} \quad (90)$$

where $N_v^{(v)} = \#(\{w_{\widetilde{dn} \neq dn} = v \text{ AND } z_{\widetilde{dn} \neq dn} = i\})$

6.3.3 Putting things together

$$\begin{aligned} \Pr(z_{dn} = i | \mathbf{z}_{-dn}, \mathbf{w}) &\propto \Pr(w_{dn} | z_{dn} = i, \mathbf{z}_{-dn}, \mathbf{w}_{-dn}) \Pr(z_{dn} = i | \mathbf{z}_{-dn}) \\ &= \frac{\eta + N_{w_{dn}}^{(v)}}{V\eta + N^{(v)}} \frac{\alpha + N_i^{(d)}}{K\alpha + N^{(d)}} \end{aligned} \quad (91)$$

where:

- $N_k^{(d)} = \#(\{z_{\widetilde{dn} \neq dn} = i\})$
- $N_v^{(v)} = \#(\{w_{\widetilde{dn} \neq dn} = v \text{ AND } z_{\widetilde{dn} \neq dn} = i\})$

6.3.4 What about β and θ_d

- **Exercise** think about what you are going to do for β and θ_d when \mathbf{z} are available
